BASIC INFORMATION ABOUT RAM AND ROM

There are two different <u>sections</u> in the <u>main memory</u> known as RAM and ROM. RAM (Random Access Memory) is used for the <u>temporary storage</u> of the user's programs and data. It is called random access because information can be written to or read from any cell with equal <u>speed</u> and <u>ease</u>. However, when information is written to a cell in RAM, any information <u>previously</u> stored there is <u>destroyed</u>. Furthermore, when the computer is <u>switched off</u>, all the information stored in Ram is lost.

<u>Permanent</u> storage of information is provided by ROM (Read Only Memory). The information stored in ROM is not lost when the computer is switched off.

However, as the name <u>suggests</u>, the computer can only read information stored in ROM but cannot put information into it. The information stored in ROM usually <u>includes</u> such things as the <u>instructions</u> necessary for the <u>basic operation</u> off he computer and the languages which the computer uses. ROM is normally programmed by the computer <u>manufacturer</u> and cannot be changed. However, <u>programmable</u> ROM <u>chips</u> (PROMs) can be used to allow the user to permanently store his own programs. This can be done only by using a special programming <u>device</u>. <u>Erasable</u> PROMs (EPROMs) were also <u>available</u>. Programs stored on EPROMs can be removed using ultraviolet light; then the EPROM can be reprogrammed.

<u>Electrically</u> erasable programmable read-only memory (EEPROM) chips remove the biggest <u>drawbacks</u> of EPROMs, <u>e.g.</u> the chip does not have to be removed to be rewritten. Flash memory is a type of EEPROM. It works much faster than <u>traditional</u> EEPROMs because it writes data in chunks, usually 512 bytes in size.
